

Calling your kid 'fat' could be counterproductive

June 1 2016

(HealthDay)—Two studies highlight the complex relationship between

parents' perceptions and their children's weights.

One study found that no matter a child's actual [weight](#), those whose parents believed they were [overweight](#) gained more weight. The other study found that more than 82 percent of parents underestimate the weight of their overweight or obese children.

The first study included more than 3,500 Australian children, aged 4 to 5 years at the start of the study. Of those children, nearly 20 percent were overweight or obese and more than 75 percent were normal weight. Only 20 percent of parents of children who were overweight correctly identified their child as being overweight.

But regardless of weight, children whose parents believed they were overweight gained more weight by age 13 than those whose parents correctly or incorrectly believed they were the right weight, according to the report.

"Contrary to popular belief, parental identification of child overweight is not protective against further weight gain, regardless of whether or not the child actually is overweight. Rather, it is associated with more [weight gain](#) across childhood," wrote study author Eric Robinson, from the University of Liverpool in the United Kingdom, and a colleague.

The study authors added that further research is needed to understand how parental perceptions of child weight may counterintuitively contribute to obesity.

The authors noted there is growing evidence that the stigma of being labeled overweight may lead children to overeat and change the way parents interact with their child, such as giving them food for comfort.

The study was presented Tuesday at the European Obesity Summit in

Sweden and was also published online May 31 in the journal *Pediatrics*.

The second study included the parents of more than 2,800 children from the Netherlands. The youngsters were 5 to 6 years old. Researchers found that 70 percent of parents correctly estimated their child's weight.

However, among parents of overweight or obese children, 82 percent underestimated their child's weight, the study revealed.

Parents in families where more than half the members were overweight were more likely to underestimate the weight of overweight and obese children than parents in families where less than half the members were overweight, the findings showed.

The study also found that [socioeconomic status](#) affected the rates of overweight and [obese children](#)—the rate was 16 percent in poor families compared to 11 percent in wealthy families.

Socioeconomic status also appeared to play a role in whether or not parents recognized that their children were overweight or obese. About one-third of wealthier parents correctly identified excess weight in their kids. By contrast, under 20 percent of [parents](#) from low or moderate socioeconomic families were able to do so, the study authors found.

"Parents are unlikely to adequately perceive overweight in their children. Perception of overweight and obesity in [children](#) concerns underestimation in four out of five cases," Grietje Lijklema, from the University Medical Center Groningen in the Netherlands, and colleagues wrote.

"Parents with high socioeconomic status are better at correctly perceiving their child is overweight but, overall, perception of a child's weight depends the most on the degree of overweight within the child's

family," the researchers reported.

This study was also presented Tuesday at the [obesity](#) meeting. The findings by Lijklema's team should be considered preliminary until published in a peer-reviewed journal.
