

Case report describes four breast cancer cases post transplant

September 11 2018

	Name: Address: Organ availability:
--	--

(HealthDay)—A single multiorgan donor transmitted breast cancer to

four transplant recipients, according to a case report published recently in the *American Journal of Transplantation*.

Yvette A.H. Matser, from the VU University Medical Center in the Amsterdam, and colleagues reported four cases of [breast cancer](#) transmission to transplant recipients from a single organ donor. The donor had no relevant medical history and donated her kidneys, lungs, liver, and heart. The heart recipient died five months later from sepsis.

The authors note that with 16 months to six years after transplantation, the other four recipients developed donor-derived breast cancer, which was proven by DNA microsatellite. As a result of the donor-derived breast cancer, the double-lung recipient, left-kidney recipient, and liver recipient died. After diagnosis of the breast cancer in the right-kidney recipient, the patient underwent transplant nephrectomy, his immunosuppression was stopped, chemotherapy was initiated, and despite having widely metastasized disease he achieved complete remission.

"This extraordinary case points out the often fatal consequences of donor-derived [breast cancer](#) and suggests that removal of the [donor](#) organ and restoration of immunity can induce complete remission," the authors write.
