The first double-blind, randomized, placebo-controlled study was published in the *New England Journal of Medicine*. The researchers discovered that patients treated with the drug were on average sick for less time – an average of 11 days versus 15.

They also found some evidence that the drug appeared to slightly reduce

severity of the disease, and to slightly reduce the <u>fatality rate</u>. There was no indication that Remdesivir could be used to completely cure COIVD-19. More studies are needed to determine effective dosing strategies to reduce severity and duration of illness, and to better understand the impact of the <u>drug</u> on different kinds of patients.
