Overweight and obesity were associated with higher risks of several common cancers in a 40-year, nationwide Danish study.

In the *Journal of Internal Medicine* study, there were 20,706 cancers among 313,321 adults diagnosed with overweight and [obesity](#) compared with 18,480 cancers that were expected based on information from the [general population](#). This corresponds to a 12% higher risk associated with overweight and obesity.

Having type 2 [diabetes](#) or alcoholism-related diseases in addition to overweight or obesity was linked with even higher risks.

The increased risk was seen for cancers previously identified as obesity-related, including pancreatic and postmenopausal breast cancers, as well as for blood and neurological cancers.
