

Do you really need to drink 8 glasses of water a day? An exercise scientist says 'no'

The warmer weather and longer days have inspired reminders to "stay hydrated" and drink eight glasses of water—or about two liters—a day.

Not to burst anyone's [water bottle](#), but healthy people can actually [die](#) from drinking too much [water](#). I am an [exercise physiologist](#), and my research focuses on [overhydration](#) and how drinking too much water

affects the body. Since water—and sodium—balance is essential to life, it is [extremely rare](#) for people to die from drinking too much—or too little—fluid. In most cases, your body's finely tuned molecular processes are unconsciously taking care of you.

Water out, water in

As spring unfolds, hydration challenges take root across [schools](#), [sports](#) and [workplaces](#). These heavily marketed hydration challenges serve to cultivate both camaraderie and friendly competition to ensure that we drink compulsory amounts of water throughout the day.

Hydration and "[Gallon Challenges](#)" support the widely held belief that [water consumption](#) beyond physiological need—or thirst—is healthy.

But this is not so. Individual body water needs—intake—are primarily based upon how much water people lose. How much water each person needs to drink mainly depends on [three factors](#):

- Body weight. Bigger people need more water.
- Environmental temperature. When it's hotter, people sweat and lose water.
- Physical activity levels. Increased exercise intensity increases sweat water losses.

Therefore, a "one size fits all" fluid replacement strategy, such as drinking eight glasses of eight ounces of water per day, is inappropriate for everyone.

It remains [unclear where the "8 x 8" water intake recommendation](#) comes from. Perhaps, this two-liter intake threshold is derived from a misinterpretation of original recommendations offered by the [U.S. Food and Nutrition Board in 1945](#) as well as the [2017 European Food Safety](#)

[Authority](#), which states the daily recommended amount of water includes all beverages plus the moisture contained in foods.

This means that the moisture contained in foods, especially fresh fruits, sodas, juices, soups, milk, coffee and, yes, even beer, contributes to this daily recommended water requirement. These guidelines go on to suggest that most of the recommended water content can be accomplished without drinking additional cups of plain water.

And, it is important to note that while [alcohol has diuretic properties](#)—ethanol acts directly on the kidneys to make us pee more—[caffeinated beverages, like tea and coffee, do not increase urinary water losses](#) above the amount of water contained in these beverages.

King kidney

Now, you may be wondering why this is so. After all, you've heard from a lot of people that you need to drink more, more, more.

Because total body water balance, or what we exercise scientists call homeostasis, is complicated, mammals survive by making [real-time adjustments at the kidney](#). That's why when it comes to hydration, our kidneys are king.

Within each [kidney](#)—we need only one (i.e., we are born with a spare, just in case) – is an [undercover network of aquaporin-2 \(AQP-2\) water channels](#) that respond to a [hormone](#) called arginine vasopressin. This is the body's main anti-diuretic (water retention) hormone. It is secreted by the posterior pituitary gland in response to nerve signals sent from specialized [brain sensors](#) which detect subtle changes in water balance. These specialized sensors are called circumventricular organs.

The kidneys will make molecular adjustments to both underhydration

and overhydration within [40 seconds](#) in response to any upset in the water balance. These adjustments result from the mobilization armies of AQP-2 water channels, numbering about [12 million per collecting duct cell](#).

This is why when we drink more water than our body needs—above thirst—we immediately have to pee out any excess water. Or when we forget our water bottle during practice, we stop peeing to conserve body water. This quick coordinated action between the [brain, cranial nerves and kidneys](#) is far more efficient and precise than any phone app, gadget or personalized recommendation available.

Is there anything good to come out of this?

Data suggests that drinking about two liters of water per day [reduces kidney stone formation](#) in people with a history of kidney stones and decreases the number of [bladder infections](#) in people with a history of bladder infections.

Improvement in [skin complexion, kidney function](#) and [constipation](#), with increased water consumption, are not clearly supported by science. Drinking extra water alone [does not help kids lose weight](#) unless water intake replaces the ingestion of higher-caloric beverages, such as soda, or makes people feel "[full](#)" before meals.

Drinking water can affect some people's mental state. Some studies report [better cognitive performance](#) after increasing water intake; while females with anxiety report [compulsive water intake makes them feel better](#), likely from activation of [reward circuits](#) that increase dopamine. Many [schizophrenic patients are compulsive water drinkers](#), stating that "[voices](#)" tell them to drink and that drinking water suppresses these voices.

Of note, brain imaging studies confirm that superfluous drinking is [unpleasant](#) and requires [greater muscular effort](#) than drinking when thirsty. Our brain tries to discourage chronic overdrinking, or polydipsia, because "[social polydipsia](#)" causes chronic peeing (polyuria), which can lead to internal plumbing modifications such as [bladder distention, ureter dilation, hydronephrosis and renal failure](#).

So, do you need to drink eight glasses of water per day? Unless you are thirsty, [drinking](#) extra water will probably not offer superior health benefits but probably is not harmful either. However, if kidneys could talk, they would say that hydration challenges represent nothing more than highly marketed peeing contests.
