A new study published in *Cancer Medicine* indicates that exosomes, or small bubbles that transport molecules from one cell to another, can be effective vehicles for delivering cancer treatments to tumors.

In the study, researchers used exosomes produced by [cells](#) called adipose-derived [mesenchymal stem cells](#) (ADSCs) to deliver an RNA-based anti-cancer treatment (miR-138-5p) to bladder cancer tumors in mice.

"The present results reveal that ADSC-derived exosomes are an effective delivery vehicle for small molecule drugs *in vivo*, and exosome-delivered miR-138-5p is a promising therapeutic agent for bladder cancer treatment," the authors wrote.
